Optional Lab: Gradient Descent for Logistic Regression

Goals

In this lab, you will:

- update gradient descent for logistic regression.
- explore gradient descent on a familiar data set

Data set

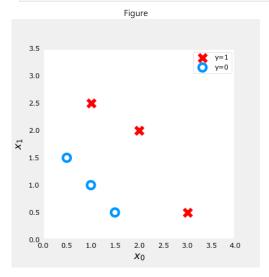

Let's start with the same two feature data set used in the decision boundary lab.

```
In [2]: X_train = np.array([[0.5, 1.5], [1,1], [1.5, 0.5], [3, 0.5], [2, 2], [1, 2.5]])
y_train = np.array([0, 0, 0, 1, 1, 1])
```

As before, we'll use a helper function to plot this data. The data points with label y=1 are shown as red crosses, while the data points with label y=0 are shown as blue circles.

```
In [3]: fig,ax = plt.subplots(1,1,figsize=(4,4))
plot_data(X_train, y_train, ax)

ax.axis([0, 4, 0, 3.5])
ax.set_ylabel('$x_1$', fontsize=12)
ax.set_xlabel('$x_0$', fontsize=12)
plt.show()
```

Logistic Gradient Descent

Recall the gradient descent algorithm utilizes the gradient calculation:

repeat until convergence: {
$$w_j = w_j - \alpha \frac{\partial J(\mathbf{w},b)}{\partial w_j} \qquad \qquad \text{for j} := 0..\text{n-1}$$

$$b = b - \alpha \frac{\partial J(\mathbf{w},b)}{\partial b}$$
 }

Where each iteration performs simultaneous updates on w_j for all j, where

Gradient descent for logistic regression

repeat {
$$w_j = w_j - \alpha \left[\frac{1}{m} \sum_{i=1}^m \left(f_{\overline{w},b}(\overline{\mathbf{x}}^{(i)}) - \mathbf{y}^{(i)} \mathbf{x}^{(i)} \right] \right]$$
 Same concepts:
$$b = b - \alpha \left[\frac{1}{m} \sum_{i=1}^m \left(f_{\overline{w},b}(\overline{\mathbf{x}}^{(i)}) - \mathbf{y}^{(i)} \mathbf{x}^{(i)} \right) \right]$$
 Same concepts:
$$(\text{Bearning curve})$$
 Simultaneous updates
$$(\text{Bearning curve})$$
 Vectorized implementation
$$(\text{Bearning curve})$$
 The transfer of the properties of the p

$$\frac{\partial J(\mathbf{w}, b)}{\partial w_i} = \frac{1}{m} \sum_{i=1}^{m-1} (f_{\mathbf{w}, b}(\mathbf{x}^{(i)}) - y^{(i)}) x_j^{(i)}$$
(2)

$$\frac{\partial J(\mathbf{w}, b)}{\partial w_j} = \frac{1}{m} \sum_{i=0}^{m-1} (f_{\mathbf{w}, b}(\mathbf{x}^{(i)}) - y^{(i)}) x_j^{(i)}
\frac{\partial J(\mathbf{w}, b)}{\partial b} = \frac{1}{m} \sum_{i=0}^{m-1} (f_{\mathbf{w}, b}(\mathbf{x}^{(i)}) - y^{(i)})$$
(3)

- m is the number of training examples in the data set
- $f_{\mathbf{w},b}(x^{(i)})$ is the model's prediction, while $y^{(i)}$ is the target
- For a logistic regression model

```
z = \mathbf{w} \cdot \mathbf{x} + b
f_{\mathbf{w},b}(x) = g(z)
where g(z) is the sigmoid function:
g(z) = \frac{1}{1+e^{-z}}
```

Gradient Descent Implementation

The gradient descent algorithm implementation has two components:

- The loop implementing equation (1) above. This is gradient_descent below and is generally provided to you in optional and practice labs.
- The calculation of the current gradient, equations (2,3) above. This is compute gradient_logistic below. You will be asked to implement this week's practice lab.

Calculating the Gradient, Code Description

Implements equation (2),(3) above for all w_i and b. There are many ways to implement this. Outlined below is this:

- initialize variables to accumulate dj_dw and dj_db
- for each example
 - ullet calculate the error for that example $g(\mathbf{w}\cdot\mathbf{x}^{(i)}+b)-\mathbf{y}^{(i)}$
 - ullet for each input value $x_i^{(i)}$ in this example,
 - \circ multiply the error by the input $x_i^{(i)}$, and add to the corresponding element of dj_dw . (equation 2 above)
 - add the error to dj_db (equation 3 above)
- divide dj_db and dj_dw by total number of examples (m)
- ullet note that $\mathbf{x}^{(i)}$ in numpy X[i,:] or X[i] and $x_{j}^{(i)}$ is X[i,j]

```
In [9]: def compute_gradient_logistic(X, y, w, b):
            Computes the gradient for logistic regression
             X (ndarray (m,n): Data, m examples with n features
             y (ndarray (m,)): target values
              w (ndarray (n,)): model parameters
             b (scalar) : model parameter
            Returns
             dj_dw (ndarray (n,)): The gradient of the cost w.r.t. the parameters w.
            dj_db (scalar) : The gradient of the cost w.r.t. the parameter b.
            m,n = X.shape
            # compute hypothesis
            f_wb = sigmoid(np.dot(X,w) + b)
            # compute bias derivative
            dj_db = np.sum(f_wb-y) / m
            # compute weight derivative
            dj_dw = np.dot(np.transpose(X),(f_wb-y)) / m
            return dj_db, dj_dw
```

Check the implementation of the gradient function using the cell below.

```
In [10]: X_{tmp} = np.array([[0.5, 1.5], [1,1], [1.5, 0.5], [3, 0.5], [2, 2], [1, 2.5]])
         y_{tmp} = np.array([0, 0, 0, 1, 1, 1])
         w_{tmp} = np.array([2.,3.])
         b tmp = 1.
         dj_db_tmp, dj_dw_tmp = compute_gradient_logistic(X_tmp, y_tmp, w_tmp, b_tmp)
         print(f"dj_db: {dj_db_tmp}" )
         print(f"dj_dw: {dj_dw_tmp.tolist()}" )
        dj_db: 0.49861806546328574
        dj_dw: [0.498333393278696, 0.49883942983996693]
```

Expected output

```
dj_db: 0.49861806546328574
dj_dw: [0.498333393278696, 0.49883942983996693]
```

Gradient Descent Code

The code implementing equation (1) above is implemented below. Take a moment to locate and compare the functions in the routine to the equations above.

```
In [11]: def gradient_descent(X, y, w_in, b_in, alpha, num_iters):
             Performs batch gradient descent
             Args:
              X (ndarray (m,n) : Data, m examples with n features
               y (ndarray (m,)) : target values
               w_in (ndarray (n,)): Initial values of model parameters
              b_in (scalar) : Initial values of model parameter alpha (float) : Learning rate
               num_iters (scalar) : number of iterations to run gradient descent
             Returns:
              w (ndarray (n,)) : Updated values of parameters
               b (scalar)
                            : Updated value of parameter
             # An array to store cost J and w's at each iteration primarily for graphing later
             J history = []
             w = copy.deepcopy(w_in) #avoid modifying global w within function
             b = b_{in}
             for i in range(num_iters):
                 # Calculate the gradient and update the parameters
                 dj_db, dj_dw = compute_gradient_logistic(X, y, w, b)
                 # Update Parameters using w, b, alpha and gradient
                 w = w - alpha * dj_dw
                 b = b - alpha * dj_db
                 # Save cost J at each iteration
                 if i<100000:
                                 # prevent resource exhaustion
                     J_history.append( compute_cost_logistic(X, y, w, b) )
                 # Print cost every at intervals 10 times or as many iterations if < 10
                 if i% math.ceil(num_iters / 10) == 0:
                     print(f"Iteration {i:4d}: Cost {J_history[-1]} ")
                                          #return final w,b and J history for graphing
             return w, b, J_history
```

Let's run gradient descent on our data set.

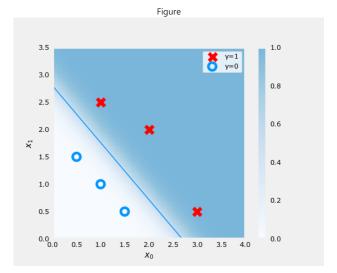

```
In [12]: w_tmp = np.zeros_like(X_train[0])
         b_{tmp} = 0.
         alph = 0.1
         iters = 10000
         w_out, b_out, _ = gradient_descent(X_train, y_train, w_tmp, b_tmp, alph, iters)
         print(f"\nupdated parameters: w:{w_out}, b:{b_out}")
        Iteration 0: Cost 0.684610468560574
        Iteration 1000: Cost 0.1590977666870457
        Iteration 2000: Cost 0.08460064176930078
        Iteration 3000: Cost 0.05705327279402531
        Iteration 4000: Cost 0.04290759421682
        Iteration 5000: Cost 0.03433847729884557
        Iteration 6000: Cost 0.02860379802212006
        Iteration 7000: Cost 0.02450156960879306
        Iteration 8000: Cost 0.02142370332569295
        Iteration 9000: Cost 0.019030137124109114
        updated parameters: w:[5.28 5.08], b:-14.222409982019837
```

Let's plot the results of gradient descent:

```
In [13]: fig,ax = plt.subplots(1,1,figsize=(5,4))
# plot the probability
plt_prob(ax, w_out, b_out)

# PLot the original data
ax.set_ylabel(r'$x_1$')
ax.set_xlabel(r'$x_1$')
ax.axis([0, 4, 0, 3.5])
plot_data(X_train,y_train,ax)

# PLot the decision boundary
x0 = -b_out/w_out[0]
x1 = -b_out/w_out[1]
ax.plot([0,x0],[x1,0], c=dlc["dlblue"], lw=1)
plt.show()
```

In the plot above:

- the shading reflects the probability y=1 (result prior to decision boundary)
- \bullet the decision boundary is the line at which the probability = 0.5

Another Data set

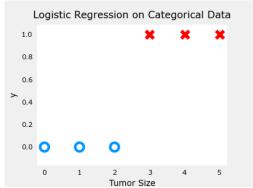

Let's return to a one-variable data set. With just two parameters, w, b, it is possible to plot the cost function using a contour plot to get a better idea of what gradient descent is up to.

```
In [14]: x_train = np.array([0., 1, 2, 3, 4, 5])
y_train = np.array([0, 0, 0, 1, 1, 1])
```

As before, we'll use a helper function to plot this data. The data points with label y=1 are shown as red crosses, while the data points with label y=0 are shown as blue circles.

```
In [15]: fig,ax = plt.subplots(1,1,figsize=(4,3))
plt_tumor_data(x_train, y_train, ax)
plt.show()
```

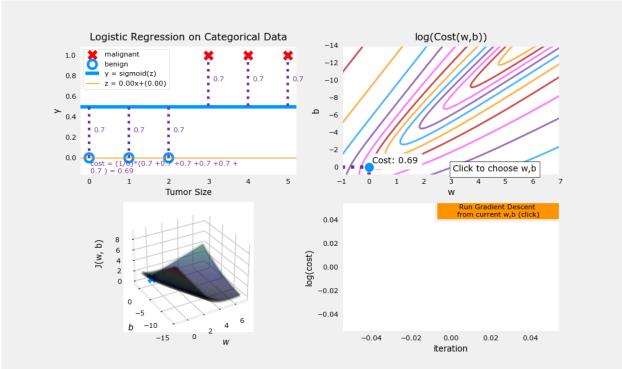

Figure

In the plot below, try:

- ullet changing w and b by clicking within the contour plot on the upper right.
 - changes may take a second or two
 - note the changing value of cost on the upper left plot.
 - note the cost is accumulated by a loss on each example (vertical dotted lines)
- run gradient descent by clicking the orange button.
 - note the steadily decreasing cost (contour and cost plot are in log(cost)
 - clicking in the contour plot will reset the model for a new run
- to reset the plot, rerun the cell

```
In [16]: w_range = np.array([-1, 7])
b_range = np.array([1, -14])
quad = plt_quad_logistic( x_train, y_train, w_range, b_range )
```

Congratulations!

You have:

- examined the formulas and implementation of calculating the gradient for logistic regression
- utilized those routines in
 - exploring a single variable data set
 - exploring a two-variable data set
